

## Principal Component Analysis (PCA) for Outlier Detection

Week 02 – Advanced Topic 3

## Agenda

- Purpose
- Method
- Results
  - Continuous variable
  - Categorical variable
- Conclusion

## Why outlier detection?

- Data Quality Improvement: Outlier detection helps identify data errors and ensures data integrity.
- **Better Model Performance:** In machine learning, outliers can have a significant impact on model training and prediction. If outliers are causing the model to perform poorly, removing them might be necessary to improve model accuracy and generalization.
- Anomaly Discovery: Outliers often represent unique events or behaviours, providing valuable insights.

## Methods: Python PCA package

### **Hotelling's T-Square:**

Hotelling's T2 is a multivariate extension of the T-test, used to measure the statistical distance of each data point from the centroid of the PCA model, which can identify outliers in the principal components space. A lower p-value T2 indicates that the observation is an outlier in terms of the principal components.

### SPE/DmodX (Squared Prediction Error or Distance to Model):

SPE/DmodX measures the squared difference between the original data points and their reconstructed values from the PCA model, focusing on the residuals not captured by the principal components. A high SPE value indicates that the data point lies far from the PCA model, suggesting it may be an outlier that doesn't fit well within the identified components.

## **Dataset: Continuous variable**

- Wine dataset from sklearn by Forina, M. et al, as part of the PARVUS project.
- Contains the results of a chemical analysis of wines grown in three different regions in Italy.

Number of Instances:	178
Number of Attributes:	13 numeric, predictive attributes and the class
Attribute Information:	<ul> <li>Alcohol</li> <li>Malic acid</li> <li>Ash</li> <li>Alcalinity of ash</li> <li>Magnesium</li> <li>Total phenols</li> <li>Flavanoids</li> <li>Nonflavanoid phenols</li> <li>Proanthocyanins</li> <li>Color intensity</li> <li>Hue</li> <li>OD280/OD315 of diluted wines</li> <li>Proline</li> </ul>

#### **SPE Results:**

- Y\_score\_spe = SPE score.
   Higher value → larger error → outlier
- Y\_bool\_spe = SPE outlier flag.
   True = Outlier

### **HT2 Results:**

- Y\_proba = Probability of each observation being an inlier. Close to 1 → low likelihood to be outlier
- **P\_raw** = P-value associated with outlier detection. P-value < 0.05 more likely to be an outlier
- Y\_score = Distance to PCA centroid. Higher values → further from center →outlier
- **Y\_bool** = HT2 outlier flag. True = Outlier

5 outliers

### Conclusion

- The PCA package, utilizing both Hotelling's T2 (HT2) and Squared Prediction Error (SPE)
  methods, is an effective tool for detecting outliers in datasets containing continuous and
  categorical variables.
- For categorical variables, it is essential to first transform the data using one-hot encoding to make them compatible with PCA.
- Although HT2 and SPE are distinct methods, they can be used in tandem to enhance the robustness of outlier detection.
- The PCA package yields two significant outcomes: a separated dataset with identified outliers
  and visual plots that illustrate the extent to which these outliers deviate within the PCA model.

#### **Pros and Cons:**

- Hotelling's T2:
  - + Detecting outliers globally and consistent
  - Specific for normal distributed data, sensitive and bias for high-correlated variables
- SPE/DmodX:
  - + Strongly detect outlier than modelled conventional PCA, able to detect local outlier
  - Complex, sensitive at selected components
